The traps of the above run as follows. Traps 100 to 331 were placed from top of terrace down to 2nd bank. Traps 32B to 27B were set on the lower bank. Traps 28B to 50B among conifers and south trending terrace. These traps were placed, in the main, in more or less concealed places to effect the *Peromyscus* & *Clethrionomys*. The route was a most difficult one to navigate on inspection tours. Set another line on the research area no B. 9-20-39. This area included a sample line of 10 traps to be used as an indicator of the feasibility of setting a full line a little later on. These traps were placed every 100 feet along the base of this ridge that runs east of the station. Bordered on the north by a willow patch and on the south by a more or less bare and rocky field. Traps placed mainly at the base of the ledges. While setting these traps found a fresh badger digging of last night. After setting lines of above made a few general recordings of the day as: Found that the marmot and pika are quiet except when giving their warning calls to the presence of a hawk or intruder. Normally they are quiet without any periodic and usual periods of calling. This afternoon at 1:30 P.M. observed two *Citellus l. east.* in an immature stage. They passed camp along the edge of the cliff outcroppings. One kept about 1 minute ahead of the other but was plain that the kept in touch of each other. They returned in about 20' but no subsequent trip this day. The *Cit. m. conso* seem to favor the open fields and particularly near camp. Big blow flies numerous and noisy. They appeared at camp just as the snow hit the tent. The bees are still favoring the conifer trees. a Badger (?) visited camp last night. Relatively free from wind during the day but toward evening the winds blew down from higher elevations and kept fives white hot. The sun left the top of the ridge due east from camp at a point on ridge where dead conifers are located. The sunny area on ridge is confined to a 100'
