

Tamiasciurus h. v. Found tracks ⁴⁰¹¹¹⁶⁻¹⁹³ that could be this form but their frequency and general distributions outside their normal conifer habit would lead one to believe probably it would be the weasel. The paw feet in some position with jumps of about $1\frac{1}{2}$ feet. If it is the true squirrel they have an entirely different distribution than I have been led to believe.

Peromyscus. New tracks. Found them, however, in greater frequency in vicinity of rock slides in lower Rock Canyon.

Hairy Woodpecker, water beetles, hawk (Swainson?) one hymenopterous insect also present. at mouth of rock Canyon took

picture 3-11-16-40 shooting down

Canyon with tintic quartzite exposure of north wall. Exposure

of $\frac{1}{5}$ sec and wide open at about 4:00 P.M. This section of the

canyon offers an interesting and rugged exposure and most

impressive when coupled with deep shadows and high lights.

The rock wren and canyon

wren were found in these

ledges. The courtturn structure is discernable at this point.

While this trip proved enjoy-

able and I personally experienced comfort, I am impressed with the fact that the closed tent and stove is the practical tent setup for winter camping, because of the conservation of the wood supply if nothing more.

NO RECORD

3-11-16-40.
