Of the specimens of *Tadarida mexicana* the greatest length is 120 mm and the shortest length is 68 mm. The greatest wing spread is 325, the shortest 115 [3]. Of the smaller bats without adult hair, about 10 per cent of the males, the testis<sup>were</sup> surrounded by fat, the other had testis more anteriorly placed and free of fat. Those encased in fat were those individuals with more fat than the others. The color varied from a light (about same color as fat) to a noticeable yellow. Only one bat showed signs of diarrhea. In very young animals the testis were angular ; others were not as well formed as adults. It is remarkable that on June 15 the females were 100% pregnant and all carried embryos, whereas on July 12 there were no pregnant females but young accompanying the females.
