

less specifically numerous, but with the exception of a very few, arrayed also in the most sombre livery, an inferiority however amply compensated by their superiority of song.

At the present time the Fauna of Europe may be fairly stated to contain four hundred and sixty-two species, of which three hundred and ten may be regarded as British; of the latter number about one hundred and seventy are permanent residents in our islands; eighty-five are summer birds of passage, visiting us from the south; and forty-five from the north make our shores their winter residence.

In our arrangement we have classed and subdivided the groups (as nearly as may be) after the plan proposed by Mr. Vigors. They form five volumes, the first of which comprises the whole of the birds of the Raptorial Order, an order containing, as implied by the name, the sanguinary and ferocious of the feathered race, among which are included not only the large tyrants of the air, the Eagles, the Falcons, the Owls, &c., which make living animals their prey; but also the Vultures, which gorge upon any loathsome carrion that chance throws in their way.

Our second and third volumes comprise the species contained in the second order, termed *Insessores*, or perching birds; an extensive order, in which are included birds varying in their powers of flight and in their habits no less than in their food; some, like the Swallow, taking their insect prey on the wing, others pursuing it among the branches of trees and thickets; others feed indifferently upon insects, their larvæ, and upon grain; and others, eminently arboreal, (such as the Woodpeckers) search for their food among the crevices of the bark of trees, for which purpose they are expressly and beautifully organized.

To these succeed the *Rasorial* and *Grallatorial* Orders, both of which are included in our fourth volume. The Pigeons, at the head of the *Rasores*, as their perching habits indicate, naturally lead from the last order to the more typical of the *Gallinaceæ*, which are well represented by the Pheasant, Partridge, and Grouse, whose food and habits it is unnecessary to describe; and from thence to the *Grallatores*, represented by the Cranes, Herons, Storks, Sandpipers and Gallinules. The first of these, the Cranes, which are more granivorous in their habits,
