

LOPHORHINUS MAGNIFICUS

Willard C. Cope

Described from the type, a single specimen, which was sent me by Mr. J. A. Rehn, of the U. S. National Museum, Washington, D. C., in 1895. The specimen was found in the collection of the U. S. National Museum, and was the only one of its kind that I have seen.

The body is elongate, with a slightly convex dorsal surface and a slightly concave ventral surface. The head is small, with a broad, flat, and slightly convex dorsal surface. The eyes are small, and the antennae are short and thick.

The thorax is small, with a broad, flat, and slightly convex dorsal surface. The wings are small, and the legs are short and thick. The abdomen is small, with a broad, flat, and slightly convex dorsal surface.

The color is a uniform, light brown. The texture is smooth, and the surface is slightly glossy. The specimen is a very fine example of the species, and is well preserved.
